

TR8: Extract traits data for plant species

Gionata Bocci
Pisa (ITALY)
boccigionata@gmail.com

October 14, 2014

1 Rationale

The **TR8** package has been built in order to provide the user with the possibility of easily retrieving traits data for plant species from the following publicly available databases:

Biolflor <http://www2.ufz.de/biolflor/index.jsp> [5]

Ecological Flora of the British Isles <http://www.ecoflora.co.uk/> [3]

LEDA traitbase <http://www.leda-traitbase.org/LEDAportal/> [4]

Ellenberg values for Italian Flora [6]

Mycorrhizal intensity database [2]

Please note that not all the traits available on the listed databases are downloaded by the package: this may change in future versions of the package (ie. some functionalities may be added and more traits will be made available).

2 Installation

The **TR8** package is available on CRAN, thus it can be easily installed through:

```
> install.packages("TR8",dependencies = TRUE)
```

The option `dependencies = TRUE` takes care of installing the following packages (if they are not already installed) which are needed by **TR8** to work properly:

- `plyr`[11]
- `reshape`[10]
- `RCurl`[7]

- XML[8]
- taxize[1]
- gWidgets[9]
- gWidgetstcltk
- rappdirs

Once the package is installed, you can load it with:

```
> library(TR8)
```

Please note that:

The user is asked to always cite the data sources: the development of traits databases is a long and costly process, thus all the users of the TR8 package are asked (and reminded **every time** they load the package) to always cite the original sources of the data (see paragraph 5).

The devel version of the package is hosted on github at the following address <https://github.com/GioBo/TR8>: to use this version (instead of the stable one, released from CRAN), you'll need the devtools package (<https://github.com/hadley/devtools>):

```
> ## install the package
> install.packages("devtools")
> ## load it
> library(devtools)
> ## activate dev_mode
> dev_mode(on=T)
> ## install TR8
> install_github("GioBo/TR8")
> ## you can now work with TR8 functions
>
> ## if you want to go back and use the CRAN version
> ## already installed, simply deactivate dev_mode
> dev_mode(on=F)
```

3 Simple usage

Using the TR8 package is fairly simple: users just need to call the `tr8` function passing, as arguments, a vector of plant species names and a vector containing the codes corresponding to the traits which are to be downloaded:

```

> ## a vector containing a list of plant species names
> my_species<-c("Apium graveolens","Holcus mollis","Lathyrus sylvestris")
> ## a vector of traits
> to_be_downloaded<-c("reprod_B","strategy")
> ## now run tr8 and store the results in the my_traits object
> my_traits<-tr8(species_list = my_species,download_list = to_be_downloaded)

```

The codes to be used are contained in the available_tr8 database:

```

> ## see the first lines of available_traits database
> head(available_tr8)

```

	short_code	description	db
1	h_max	Maximum height	Ecoflora
2	h_min	Minimum height	Ecoflora
3	le_area	Leaf area	Ecoflora
4	le_long	Leaf longevity	Ecoflora
5	phot_path	Photosynthetic pathway	Ecoflora
6	li_form	Life form	Ecoflora

The database is composed of three columns:

short_code contains the codes corresponding to the traits which can be downloaded through the `tr8` function. These are the codes that should be passed to the `download_list` argument of the `tr8` function.

description contains short description of each trait (please refer to the original sources for detailed descriptions).

db refers to the databases containing the traits

Suppose the user is interested in downloading the *maximum height*, the *leaf area* and the *life form* (which are available through the *Ecoflora* database) for *Salix alba* and *Populus nigra* and store the resulting data in the `my_Data` object; the command should be:

```

> my_species<-c("Salix alba","Populus nigra")
> my_traits<-c("h_max","le_area","li_form")
> my_Data<-tr8(species_list = my_species, download_list = my_traits)

```

The `tr8` function will take care of downloading the data and store them in the `my_Data` object; you can see the results by printing them:

```

> ## see the downloaded data
> print(my_Data)

```

Or you can convert them to a data frame using the `extract_traits` function:

```

> traits_dataframe<-extract_traits(my_Data)

```

All the traits are now contained in a data frame with species as rows and columns as traits; where no trait data were available, you will see a **NA**.

In order to make the dataframe more readable, traits' names (ie. columns' names) are converted to shorter codes: to see a brief explanation of the codes used to identify the traits, use the `lookup` function:

```
> lookup(my_Data)
```

The object returned by the `lookup` function can also be stored in order to be available for further elaborations:

```
> my_lookup<-lookup(my_Data)
> head(my_lookup)
```

Up to now we've been using the `tr8` function in a non-interactive way. In order to help those user which are more familiar with a GUI approach, the function can also be run setting the `gui_config` parameter to `TRUE` (without providing any trait in the `download_list` parameter) and a multi-panel window will appear: the user is asked to choose those traits which are to be downloaded from the various databases.

For a detailed explanation of each level of a trait, please refer to the original websites (all the databases listed in the references provide the users with very precise and detailed descriptions).

Typically users will have a their vegetation data in the form of a *sites*species* dataframe (or matrix), thus they may want to extract traits data for the whole dataset (this time using the GUI to select traits), ie. :

```
> ## suppose veg_data is our dataframe with
> ## plant species as columns and sites as rows
>
> ## extract species names
> specie_names<-names(veg_data)
> ## use the tr8() function
> ## and tick those traits of interest in the pop-up window
> my_traits<-tr8(specie_names,gui_config=TRUE)
> ## print the results
> print(my_traits)
```

A NOTE OF CAUTION: searching the web is a time (and internet band) consuming activity, thus the higher the number of your plant species and the traits to be retrieved, the longer it will take to `tr8()` to complete its job. Moreover, in order not to overflow the remote databases with `http` requests, the `tr8` function will always pause between one search and the following one.

A (SECOND) NOTE OF CAUTION: some users adopt the following workflow for analysing their vegetation data:

1. insert vegetation data into a *spreadsheet file* with species as columns' and sites' as rows

2. export the spreadsheet file as a `.csv` file

3. import the `.csv` file into a **R** dataframe.

When following these steps, a dot (".") will be inserted between Genus and Species of each plant species name (i.e. column names in the **R** dataframe will not be in the form `c("Abies alba", "Salix alba")` but in the form `c("Abies.alba", "Salix.alba")`). This may cause problems for further processing of plants' species names, thus, in order to avoid this problem, please use the `check.names=F` option in `read.csv`. Eg. suppose that `my_veg_data.csv` is the `csv` file: in the **R** console, one should use:

```
> My_data<-read.csv("my_veg_data.csv",header=T,row.names=1,check.names=F)
```

4 Interpreting retrieved data

Please note that for many traits there is more than one entry in the original databases: in those cases, in order to obtain a single value the following strategy was adopted:

Quantitative traits the mean of all the values was calculated (eg. when multiple values for "Seed weight mean" are available, the mean of these value is calculated)

Qualitative traits all the values are taken into account and "joined" together in a single string (the values are separated by a score "-")

Nota bene: in some cases some traits are stored as *string* in the original databases, even though they should be treated as numbers (e.g. the number *five* is stored as a string - i.e. "5", not as the numeric value 5): in those case `tr8` function is not able to interpret that entry as a numeric, thus, applying the above mentioned criteria to merge multiple traits, strange outputs may result from `tr8`, e.g. if a species has two entries for the trait `height` - day 3 and 3.5 meters - the merged value will not be the numeric mean (3.25) but the union of the two strings ("3-3.5").

5 Citing sources of information

Users of the **TR8** package should always cite the sources of information which provided the traits data: the correct citations to be used for the retrieved data can be obtained through the `bib` method; just use:

```
> bib(my_traits)
```

6 Suggested usage

We strongly suggest to always check plant species names with the `tnrs` function (from the `taxize` package) before using the `tr8` function; thus a typical workflow would be the following:

1. Check plant species names (eg. with something like the following - please refer to the `taxize` package documentation[1] for further details)

```
> species_names<-names(veg_data)
> checked_names<-tnrs(species_names,source="iPlant_TNRS")
> print(checkered_names)
```

Check which species (rows) in the table have a "score" value lower than 1 and check their names; if needed, correct them before using the `tr8()` function.

2. Run `tr8` (in this case using the GUI):

```
> my_traits<-tr8(species_names)
> print(my_traits)
```

3. You may want to have these traits available as a data frame: just use the `extract_traits` function which uses the results of `tr8` (in this case it's the `my_traits` objects) and returns a data frame.

```
> traits_df<-extract_traits(my_traits)
```

4. Observing a big data frame inside R could be difficult, thus users may want to save the `traits_df` data frame as a `.csv` file and open that with a spreadsheet software (eg. LibreOffice)

```
>
```

7 Local storage of LEDA and Akhmetzhanova data

The LEDA Traitbase datafiles and Akhmetzhanova database are text files (either `.txt` or `.csv` files) which are available for download at the LEDA (http://www.leda-traitbase.org/LEDAportal/data_files.jsp) and at the *Ecological Archives* websites . These files are (quite) big in size, thus downloading them every time the `tr8()` function is used is a time consuming activity¹. We thus suggest the users to run the `local_storage`² function once to store a local

¹The text files are not distributed together with the `TR8` package - which would save time and memory when executing the `tr8()` function - in order to avoid possible licensing conflicts between the `TR8`' GPL license and these datasets.

²The name is quite self-explanatory...

copy of these datafiles datafiles and use that local copy every time the `tr8()` function is run and LEDA or Akhmetzhanova are requested³.

```
> ## run the function
> local_storage()
```
